

Review on the LHC Run2 results

KMI2017, 5th-7th January 2017

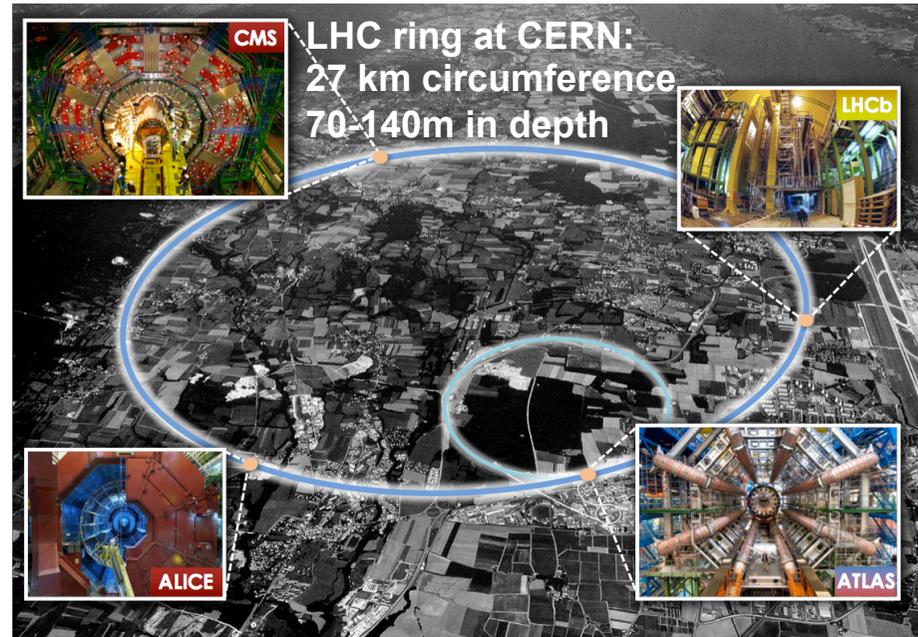

Yu Nakahama (KMI, Nagoya University)

Outline of this talk

- Introduction to LHC and the ATLAS Run2 experiment
- Review of physics results
 - Standard Model measurements
 - Higgs physics
 - Searches for New Physics phenomena; Exotics, SUSY
- Summary

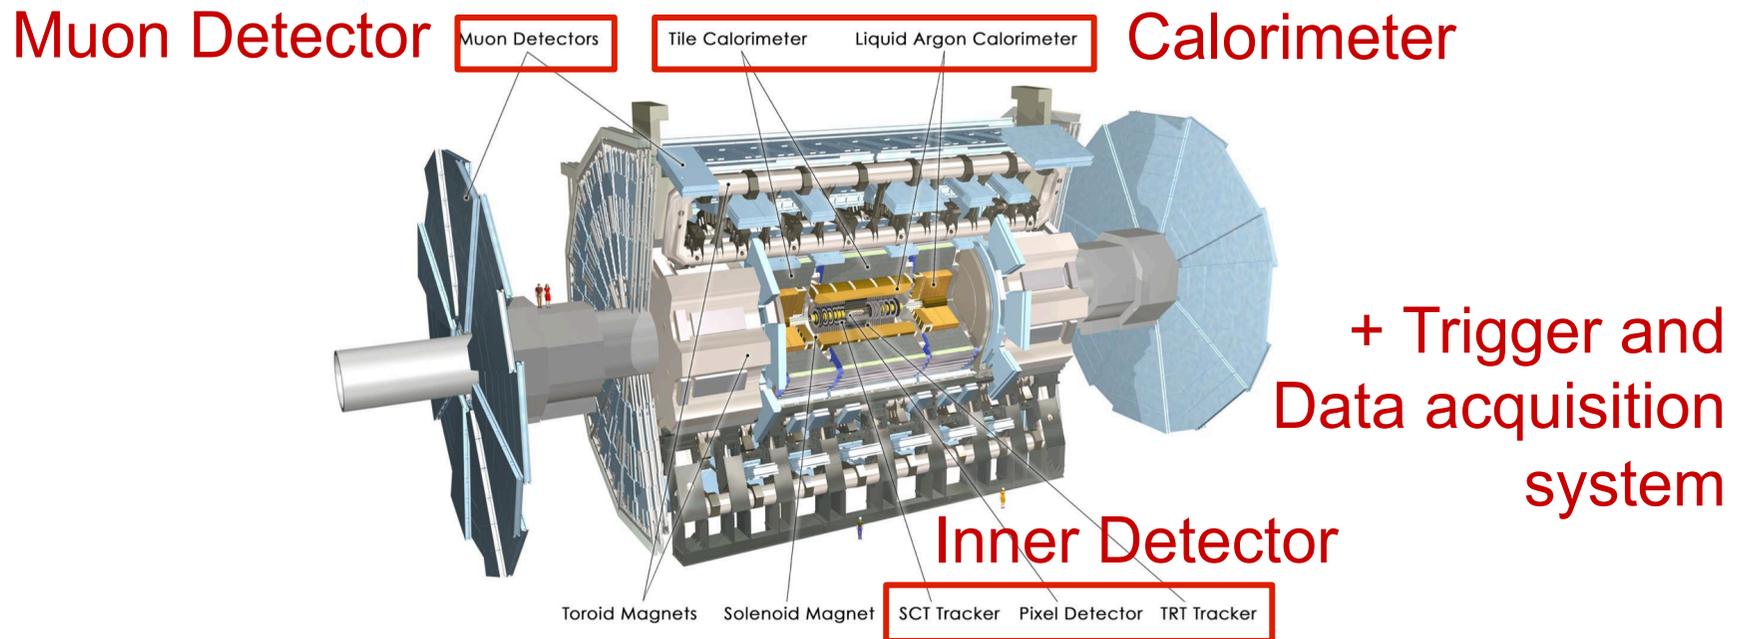

Large Hadron Collider

- LHC is an energy-frontier collider at CERN, delivering proton-proton collision events
 - to two multi-purpose detectors; ATLAS and CMS
 - to dedicated detectors; LHCb for B-physics studies and ALICE for heavy-ion studies
- Recent history and future
 - LHC Run1 (2009-2012) with p-p collisions at $\sqrt{s} = 7-8$ TeV
 - **Currently in a high-energy phase at $\sqrt{s} = 13-14$ TeV, Run2 (2015-2018), followed by a bit higher luminosity phase Run3 (2021-2023)**
 - I review recent physics highlights in this talk
 - For future, **high-luminosity LHC (2026-)** and **FCC (far beyond)** is planned
 - B. Petersen will present the future physics program
 - M. Tomoto will present muon trigger upgrade (KMI's contribution)

The ATLAS experiment

- The ATLAS detector is a multi-purpose detector that can directly explore energy scale from $O(10)$ GeV to $O(10)$ TeV

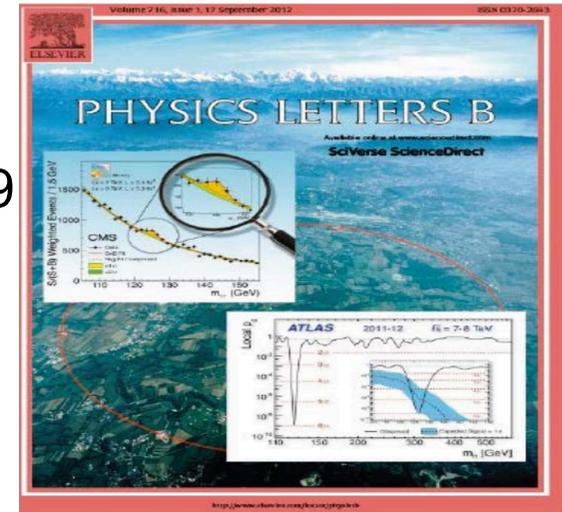

- The ATLAS experiment has around 2900 collaborators from 180 institutions across 38 countries
- KMI has been contributing to ATLAS
 - with primary focuses on “Muon Detector and Trigger system”, as well as on “Top physics and New Physics searches”

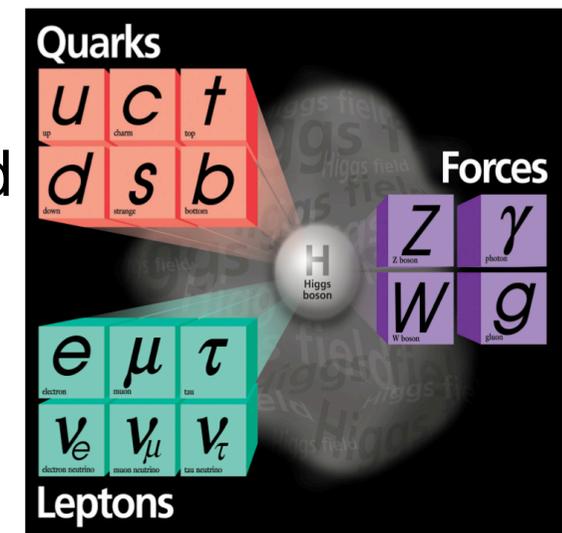

Physics highlights with the Run1 dataset

- **Higgs discovery**

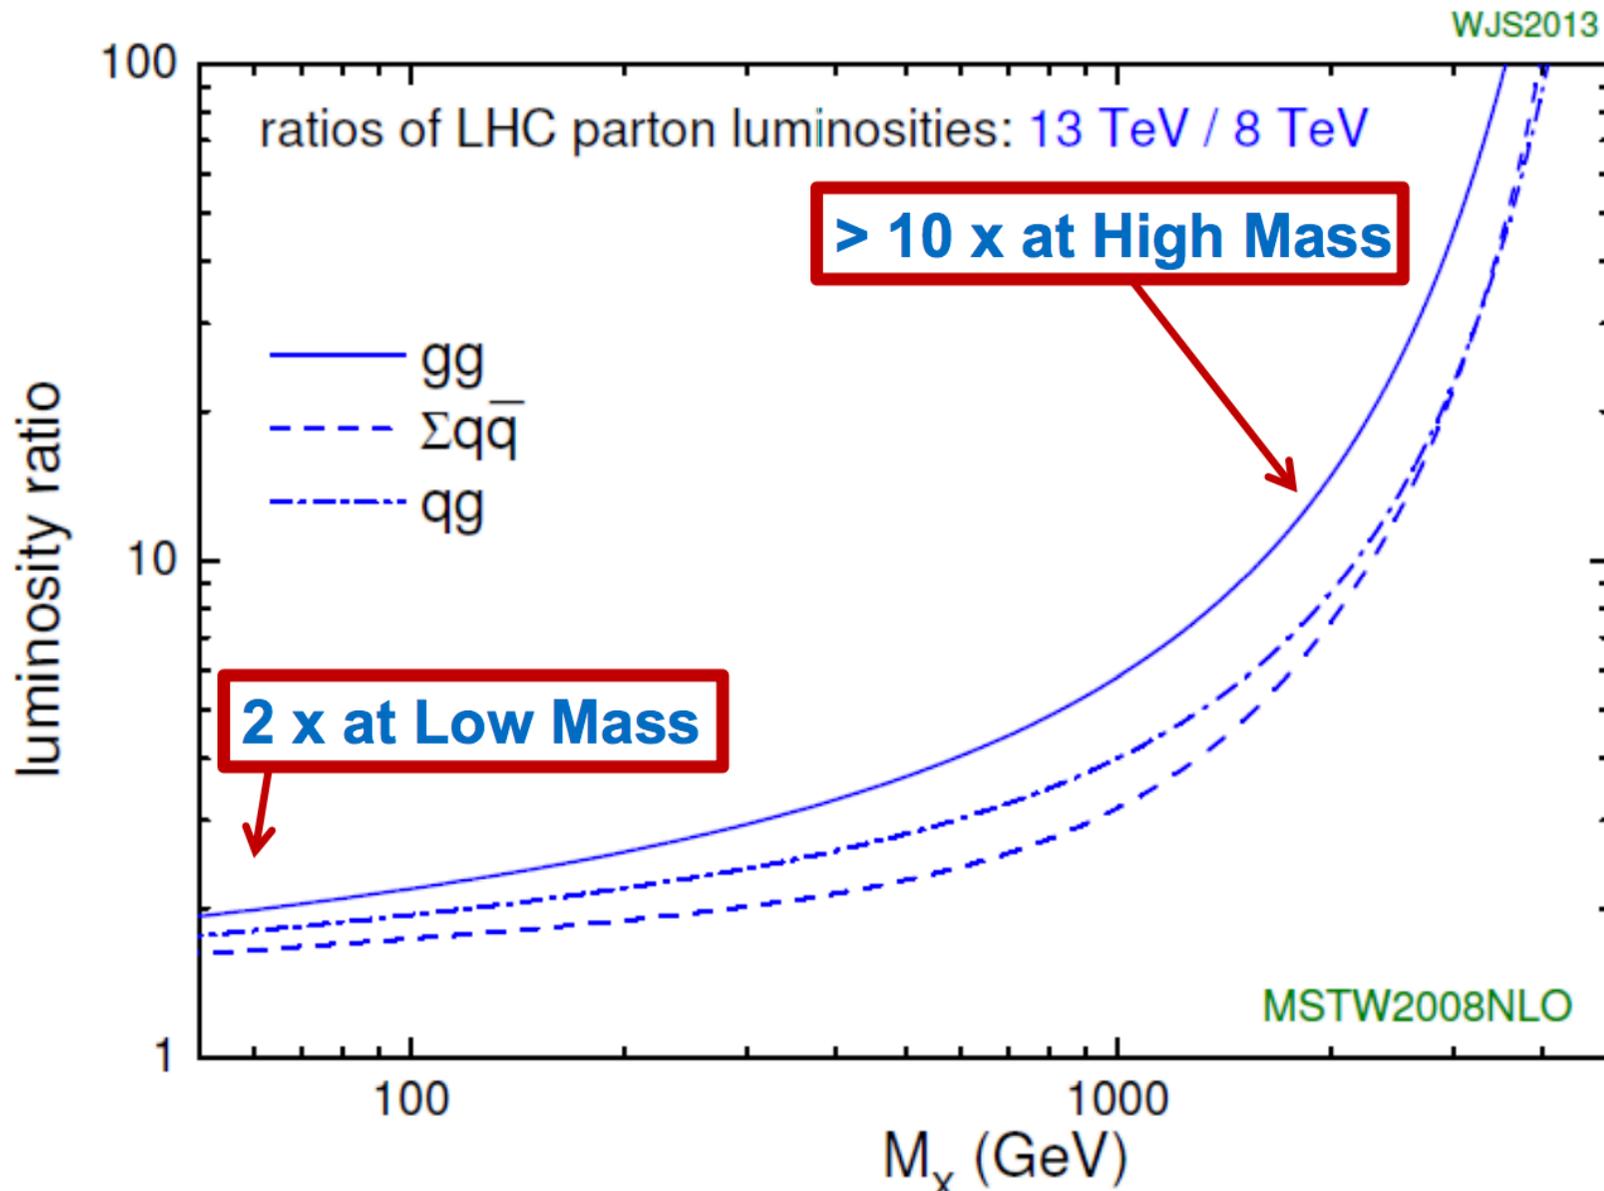

- Higgs-like particle discovery was announced on July 4th 2012 - Phys. Lett. B 716 (2012) 1-29
- March 2013: key papers on particle properties. New particle declared as “a Higgs boson”
- Citation for the 2013 Nobel Prize in Physics

- Deep and broad range of experimental results, all beautifully fitting in the Standard Model framework of elementary particle physics

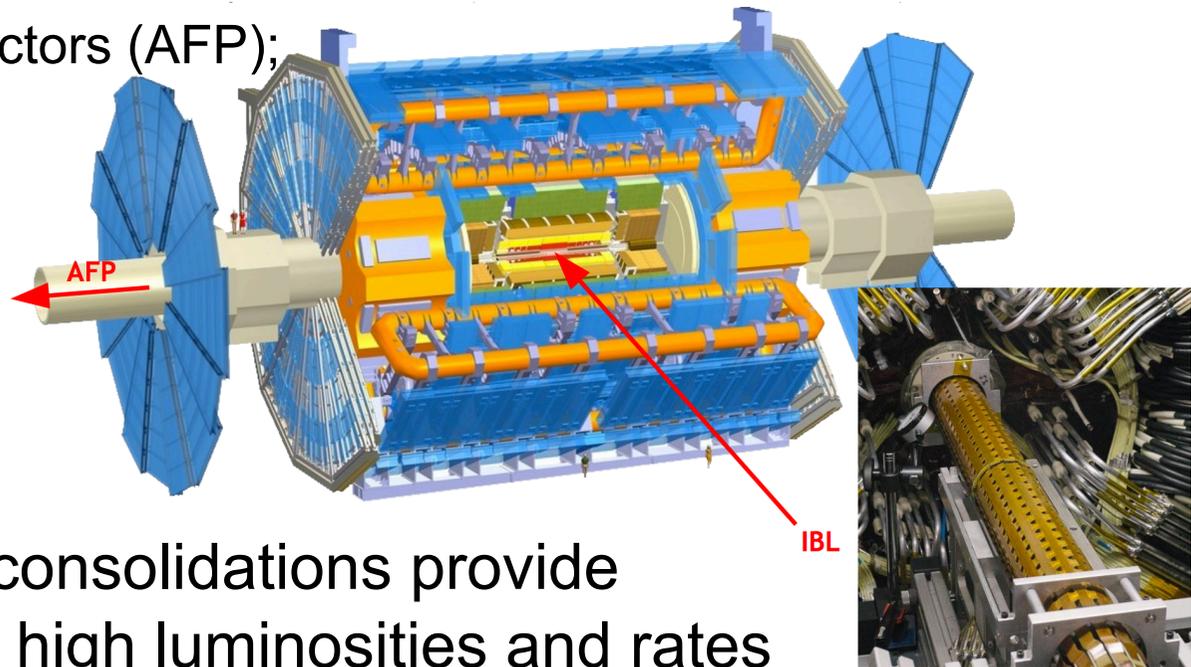

$\sqrt{s} = 13$ TeV: parton luminosity increase

ATLAS in Run2

- Primary physics focuses
 - on New Physics searches using early datasets and
 - on measurements of Higgs properties using higher-statistics datasets
- New detectors installed
 - Innermost pixel layer (IBL); 3.4cm from the interaction point
 - Forward proton detectors (AFP); 210m from IP

- In addition, various consolidations provide improved running at high luminosities and rates

ATLAS data taking in 2016

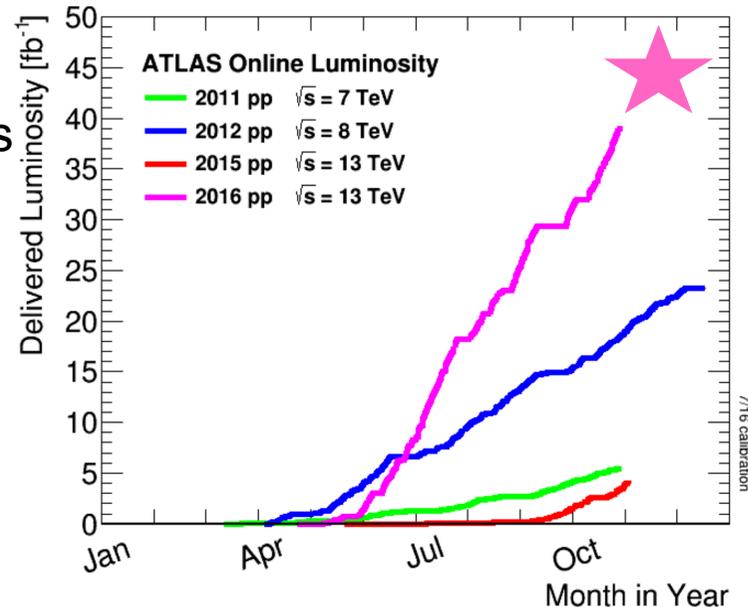

- The 2016 pp data taking lasted until 26th October
 - Set a record in peak luminosity: 1.4×10^{34}
 - Total dataset recorded $\sim 36 \text{ fb}^{-1}$ with excellent data quality; $>90\%$ of data collected usable for analyses

Operations in the ATLAS control room

- 2016 was an extremely productive year, comparing with previous years

Delivered luminosities to ATLAS (per year)

Trigger challenge in high luminosities

- Critical contribution from KMI, including menu-coordination role
- Designed and operated a complex list of trigger selections to meet varied physics, monitoring and performance requirements

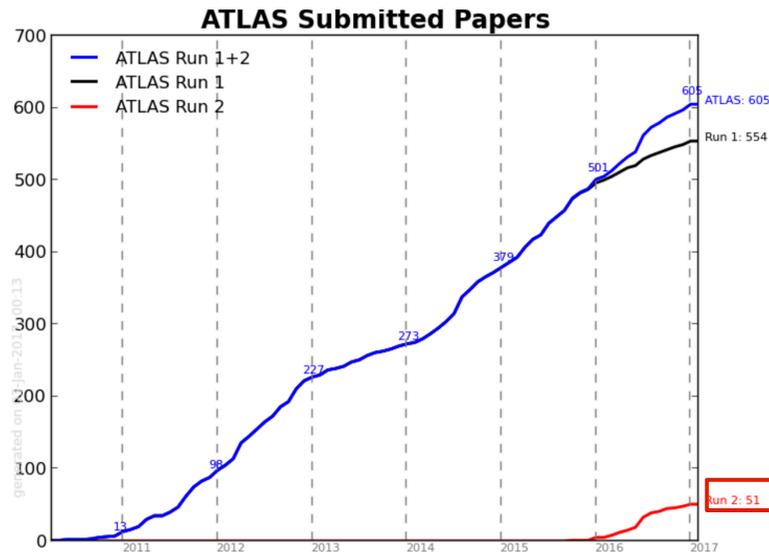

- Typically ~2000 active trigger selections, driven by the priorities in the ATLAS physics program
- Stable primary triggers
- Peak output rate at Level-1; 90kHz
- Ave. output rate at High Level to storage; 1.0kHz
- meeting detector operation and DAQ requirements

Main primary trigger	Trigger thresholds at HLT [GeV]
single leptons	Isolated μ , $p_T > 26$
	Isolated e, $E_T > 26$
E_T^{miss}	> 110 (in MHT, jet-based)
single jet	$p_T > 380$
single photon	$E_T > 140$
di-muon for B-physics	$p_T(\mu_1, \mu_2) > 6, 6 + \text{topological/mass cuts}$
di-tau	$p_T(\tau_1, \tau_2) > 35, 25 + \text{jet requirement at L1}$
di-photon	$p_T(\gamma_1, \gamma_2) > 35, 25$

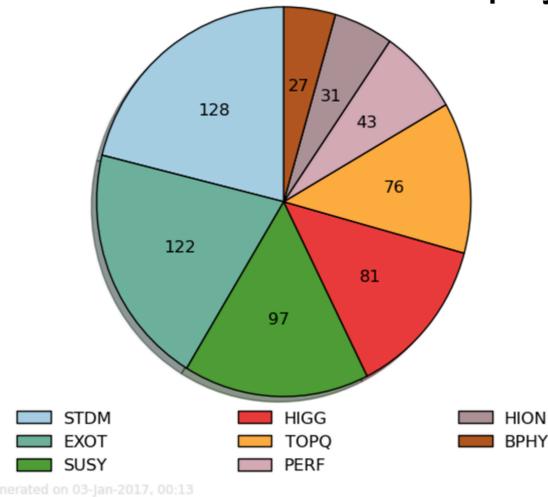

- Trigger menu for the rest of Run2 is being prepared for 2e34

Physics Results

- ATLAS has submitted 605 papers in total
 - including 51 papers using Run2 dataset

ATLAS - Papers/Lead-group
From varied physics areas

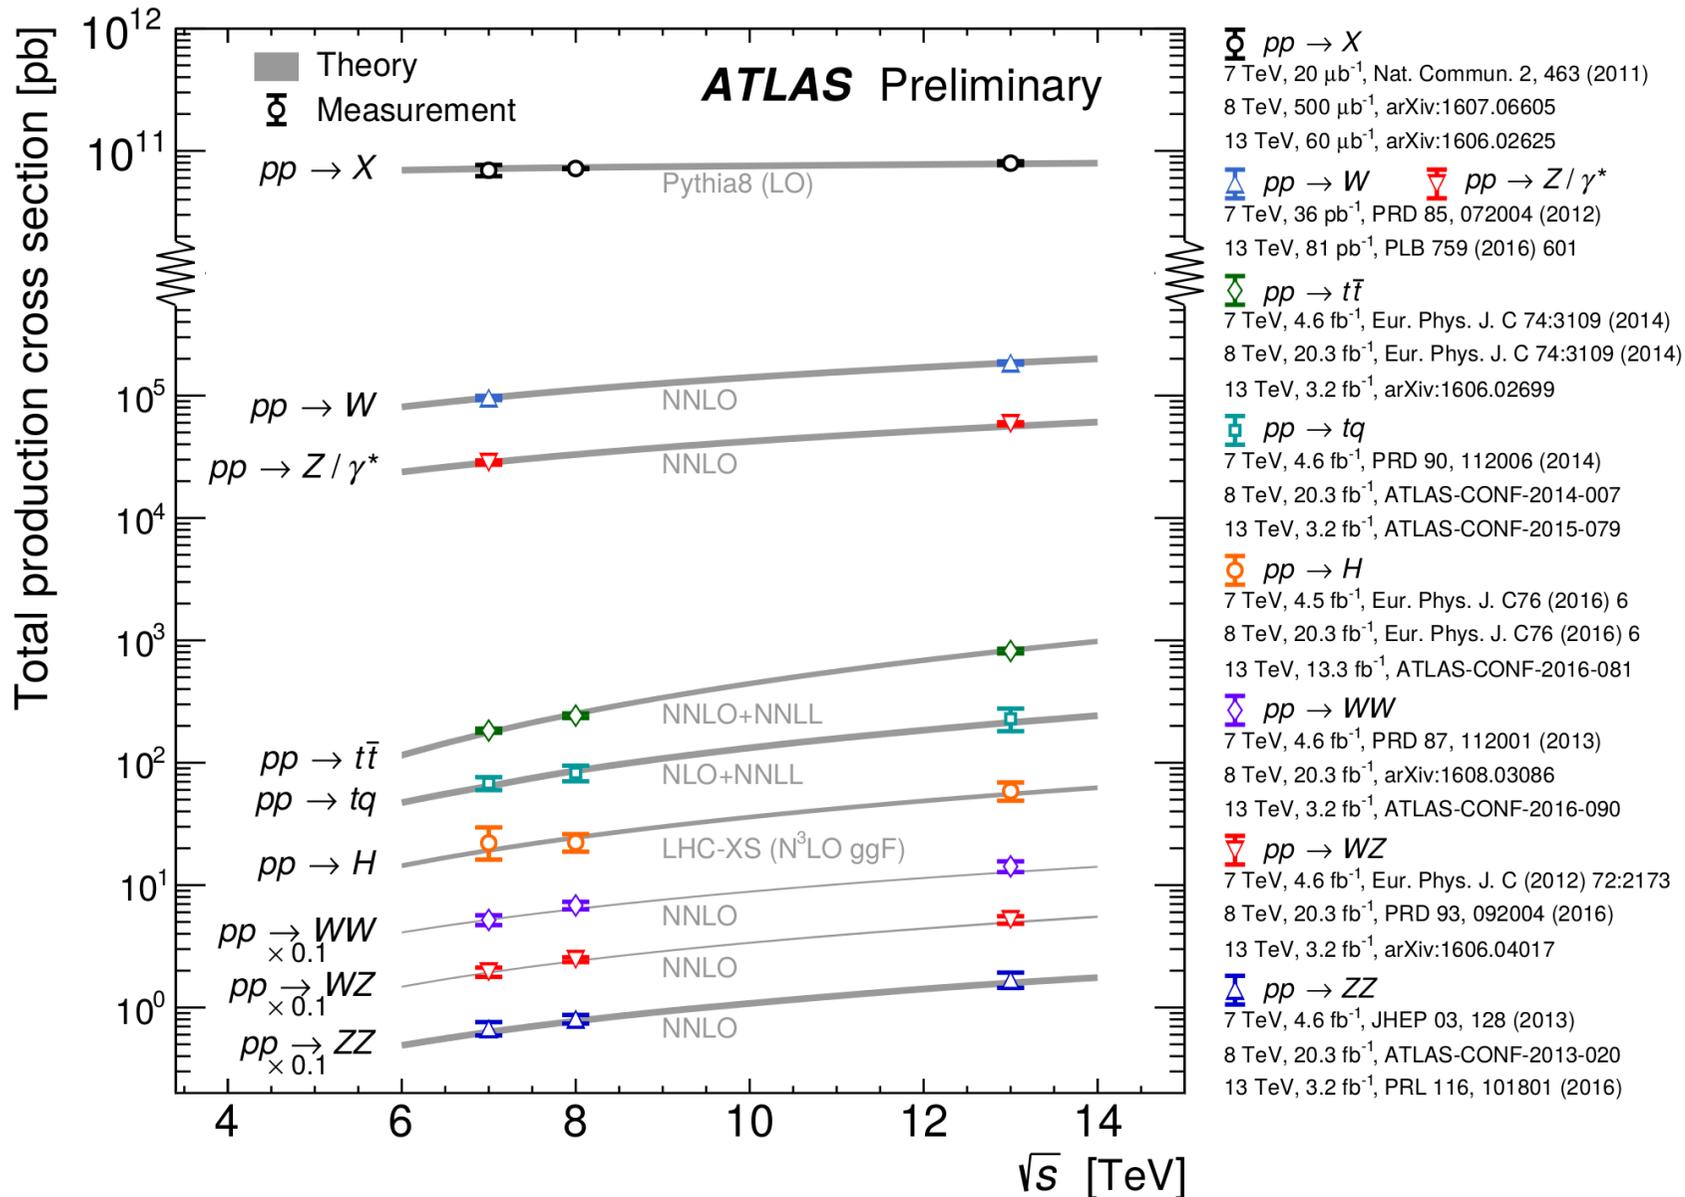

- the full list here: <https://twiki.cern.ch/twiki/bin/view/AtlasPublic>

- Following slides review a few selected highlights, mostly using 13 fb^{-1} dataset, collected up to 2016 summer
 - Disclaimer; Topics here are driven by the priorities in the Run2 ATLAS physics program, by my tastes, as well as by the KMI's contributions
 - Apologies if your favorite topics are not covered

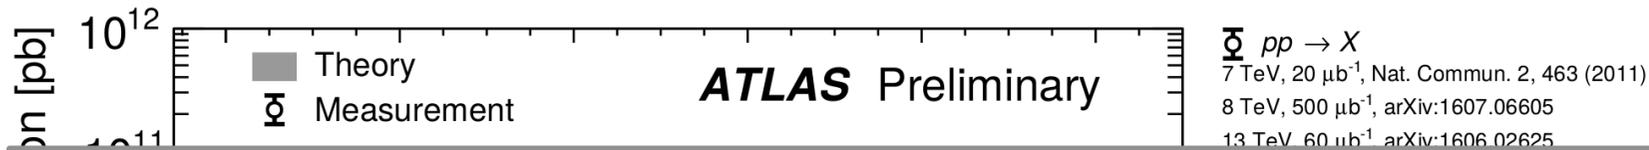

- **Measurements**

Inclusive cross-section measurements: broad range

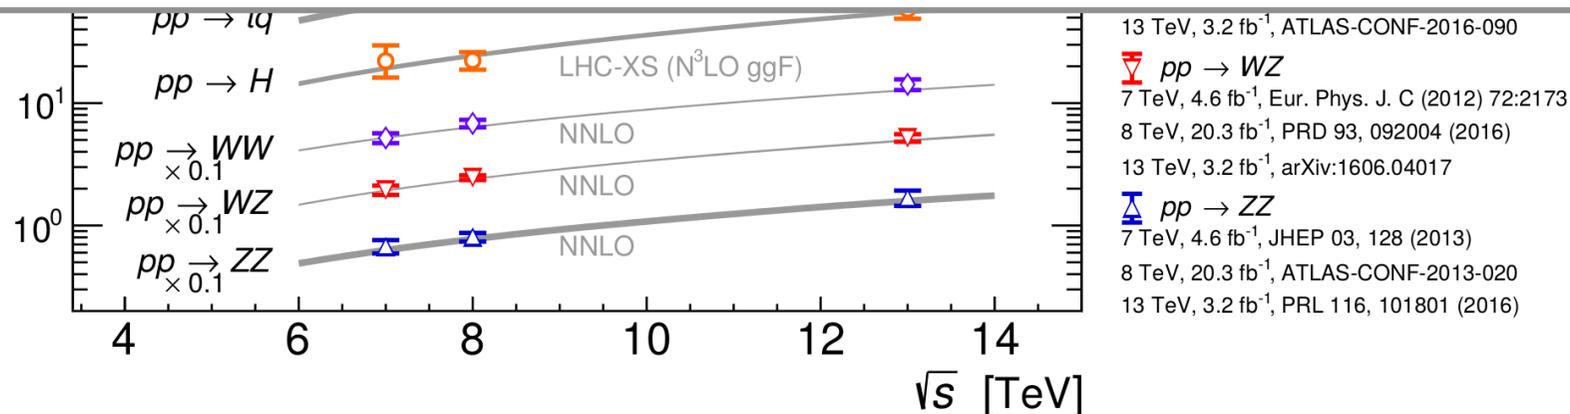

Inclusive cross-section measurements: broad range

These many measurements from Run1 and Run2 are important steps forward in physics modeling in the last years:

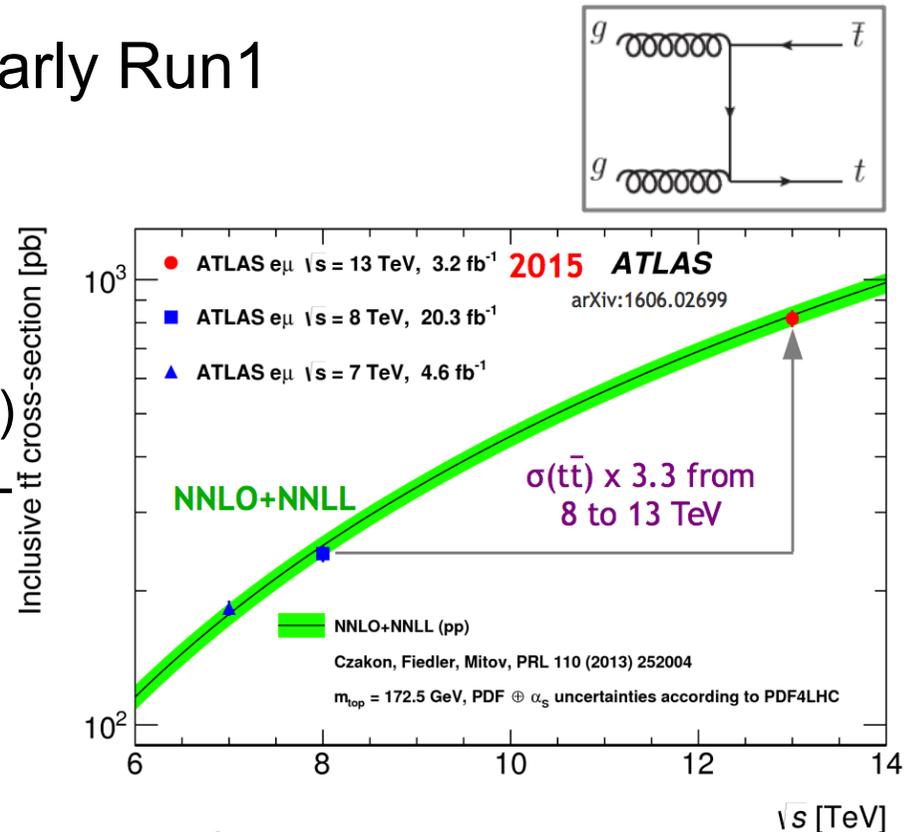

- NLO event generators – now standard
- (N)NNLO calculations increasingly available - These help to face the challenge of the precision of the LHC data

Measuring complex topologies bench-test Monte Carlo models of backgrounds to New Physics searches

ttbar cross-section measurements

- Nagoya's contributions since early Run1
- Precise measurements of inclusive ttbar cross-sections
 - Precisions $\pm(3.9-4.4)\%$ (7-13 TeV) is better than theory NNLO+NNLL predictions ($\sim 5\%$)

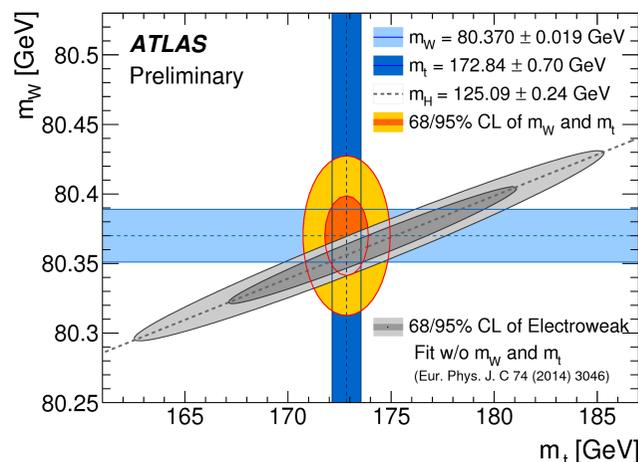

- High statistics allow detailed studies of production properties
 - e.g. differential cross-section measurements (Check poster by K. Kawade, the Nagoya ex-member)

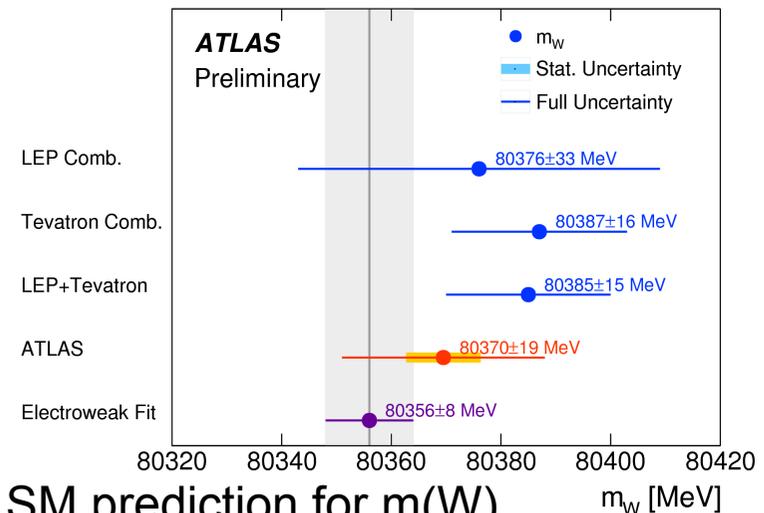

W-boson mass measurement

ATLAS-CONF-2016-113

- Precise measurement is motivated for a consistency test of the SM and a probe of BSM physics – yet with slow progress
- After long/huge efforts, the first ATLAS result using the 7 TeV dataset was released in Dec 2016
 - $m(W) = 80.370 \pm 0.019$ GeV, a competitive measurement, dominated by physics modeling uncertainties as expected
 - Consistency tests of the SM

SM prediction for $m(W)$ vs $m(t)$, assuming $m(H) = 125.09 \pm 0.24$ GeV

SM prediction for $m(W)$, assuming $m(H) = 125.09 \pm 0.24$ GeV
 $m(t) = 172.84 \pm 0.70$ GeV

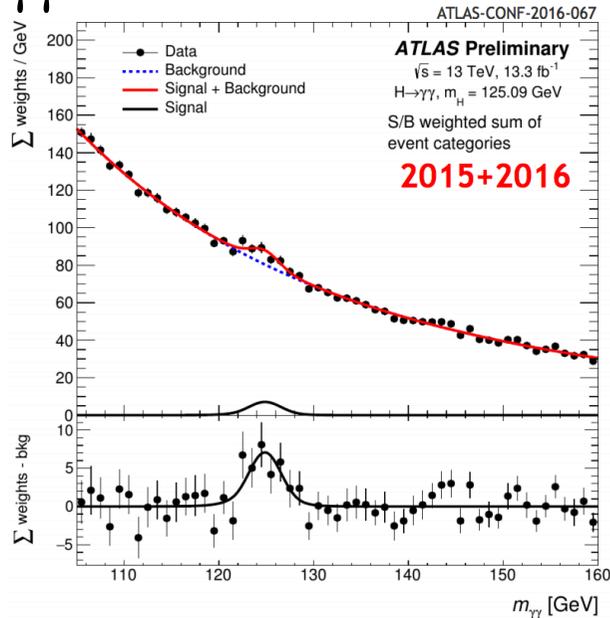

-
- Understanding the 125 GeV Higgs

Physics of the 125 GeV Higgs

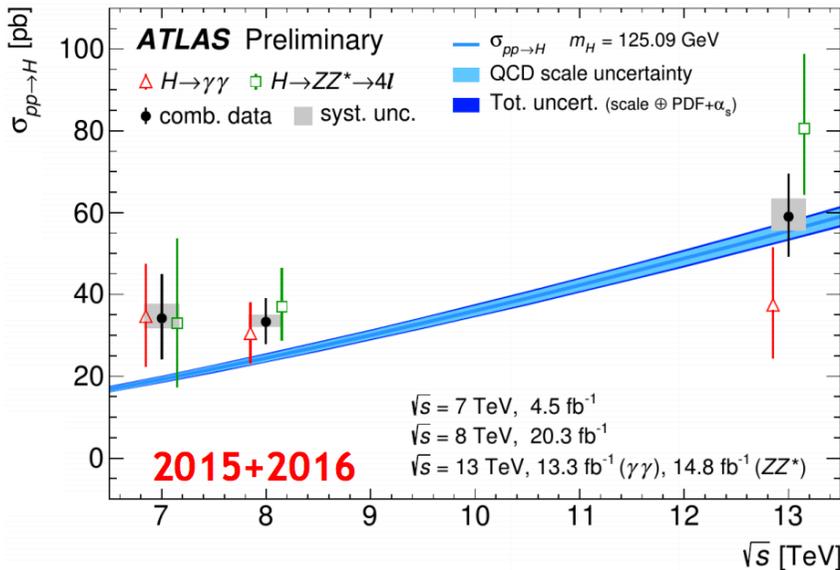

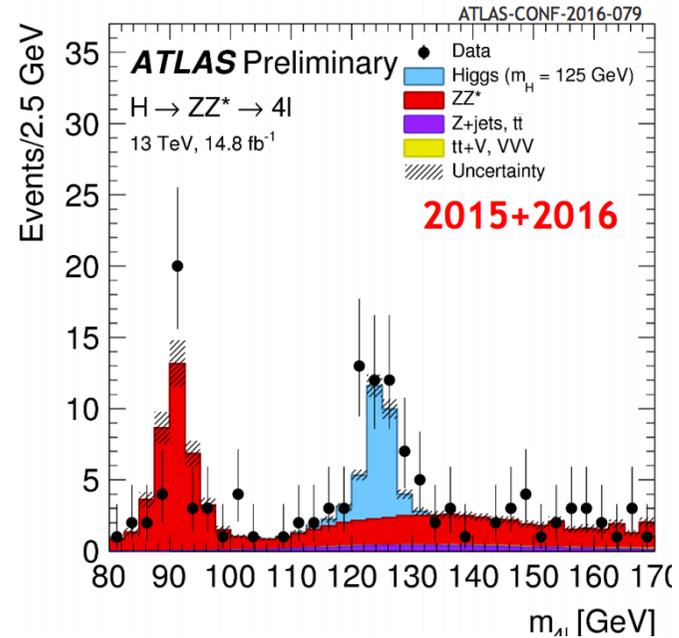

- Higgs discovery opened the door on the scalar sector
- In Run1 we measured:
 - Its spin-parity, and its mass precisely ($\pm 0.2\%$)
 - Production via gluon-fusion, vector-boson fusion, and with a W or Z
 - The decays to $\gamma\gamma$, WW, ZZ, and the fermionic decay to $\tau\tau$
- These proved true the BEH mechanism to break gauge symmetry
- However, apart from the mass, none of these measurements are yet very precise and leave room for significant deviations. Also, important modes are still unseen (bb, ttH, $\mu\mu$, $Z\gamma$, HH)
- Run2 priorities:
 - Establish and measure at 13 TeV
 - Search for ttH production to probe ttH coupling directly
 - Search for $H \rightarrow bb$ decays
 - Search for rare decays
 - Refine measurements of couplings, mass, etc
 - Expand use of H as a tool to find New Physics

Clear Higgs observation at 13 TeV in bosonic channels

$H \rightarrow \gamma\gamma$

$H \rightarrow 4\ell$

Combining $\gamma\gamma+4\ell$ channels

$$\sigma(pp \rightarrow H+X, 13 \text{ TeV}) = 59.0^{+9.7}_{-9.2} \text{ (stat.) } +4.4_{-3.5} \text{ (syst.) pb}$$

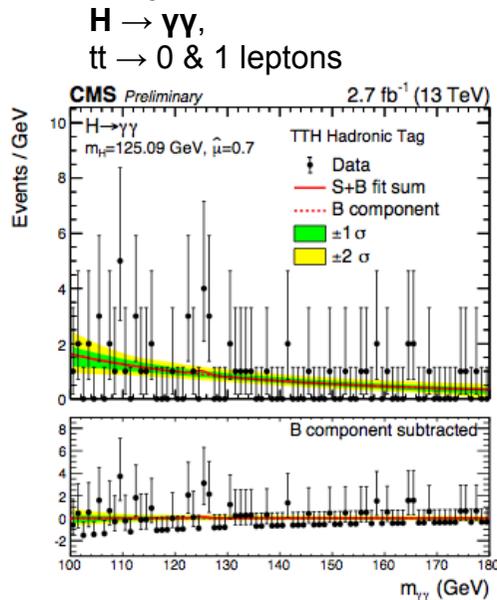

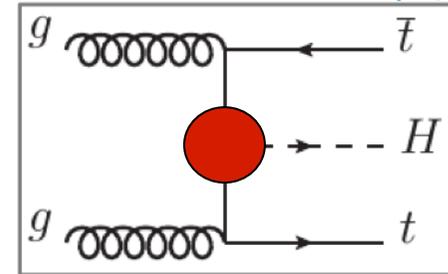

SM prediction

$$55.5^{+2.4}_{-3.4} \text{ pb}$$

Overall significance at 13 TeV $\sim 10\sigma$

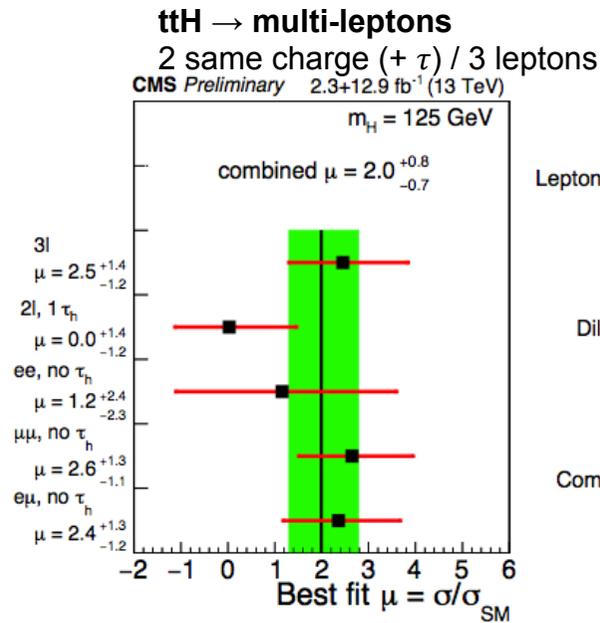

First search for ttH production at 13 TeV by CMS

- **Direct measurement of Higgs-top coupling**
- CMS showed preliminary results for ttH in all major Higgs decay channels: $\gamma\gamma$, multi-lep, bb
- *Highly* complex analyses, huge effort to get these done so quickly after data taking (already by Moriond 2016)

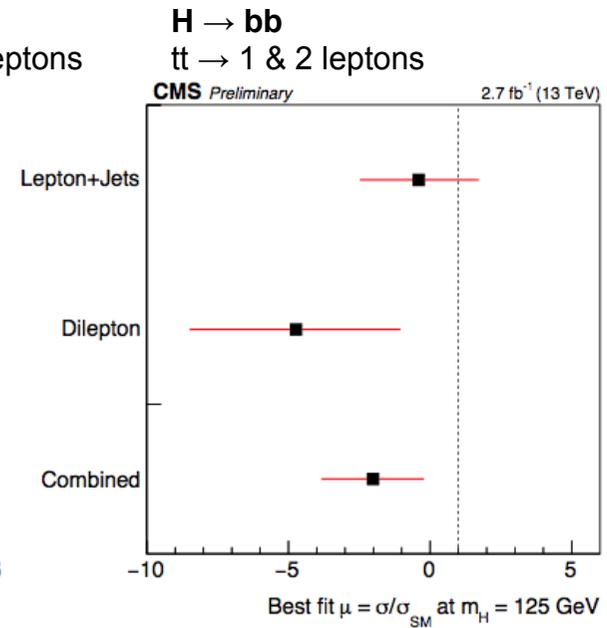

$$\mu = 3.8^{+4.5}_{-3.6}$$

CMS-PAS-HIG-15-005

$$\mu = 2.0^{+0.8}_{-0.7}$$

CMS-PAS-HIG-16-022

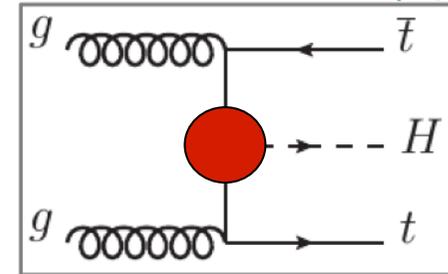

$$\mu = -2.0 \pm 1.8 < 2.6 \text{ (95\% CL)}$$

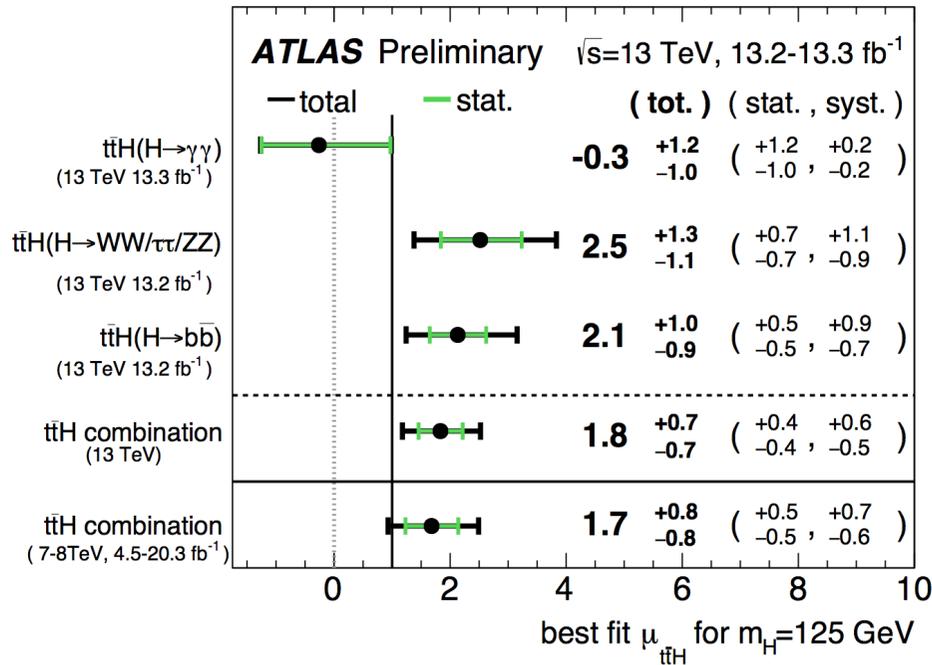

CMS-PAS-HIG-16-004

First search for ttH production at 13 TeV by ATLAS

- Direct measurement of Higgs-top coupling
- ATLAS showed preliminary results for ttH in **all major channels and their combination** at ICHEP 2016

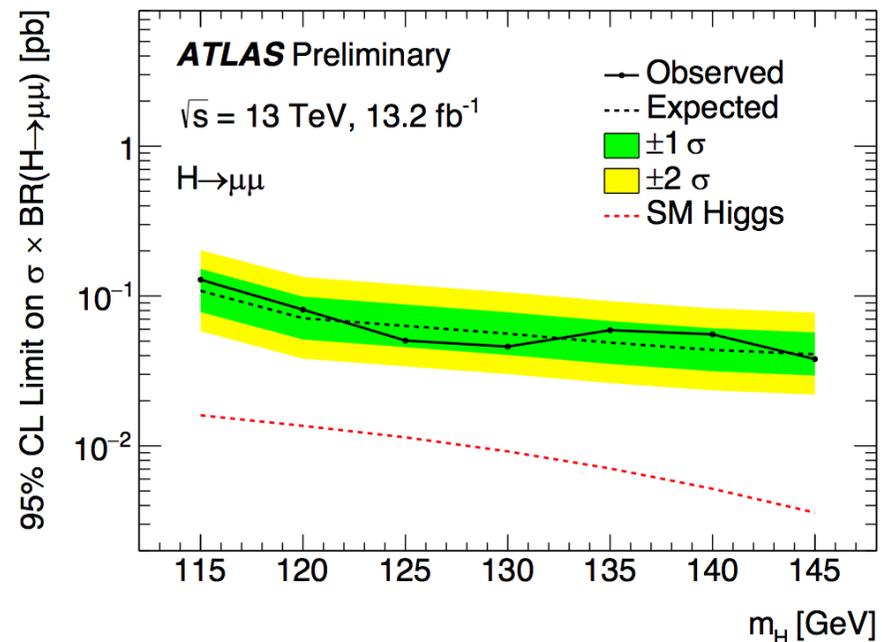

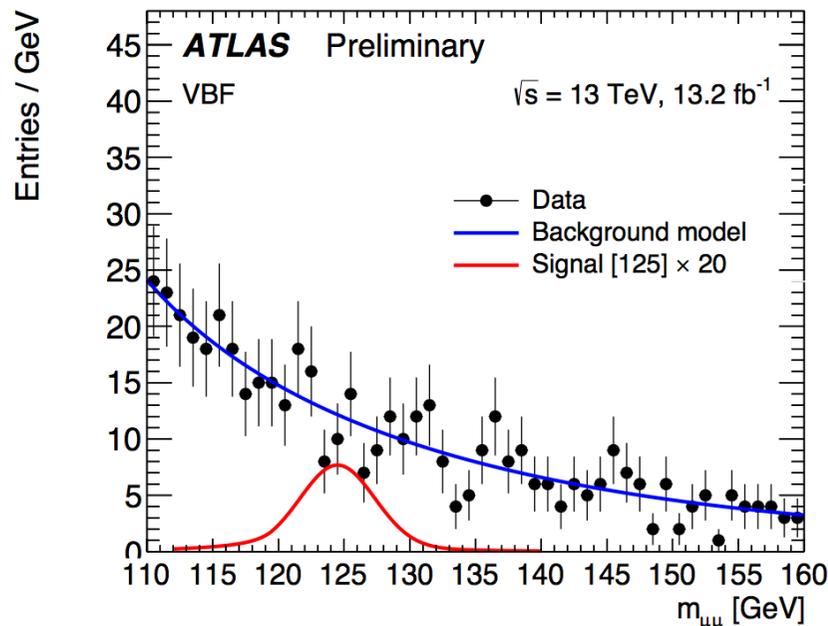

Individual channels and combination

→ Observed significance 2.8 σ
(expect 1.8 σ , improved sensitivity over Run1)

Searches for rare Higgs decays e.g. $H \rightarrow \mu\mu$

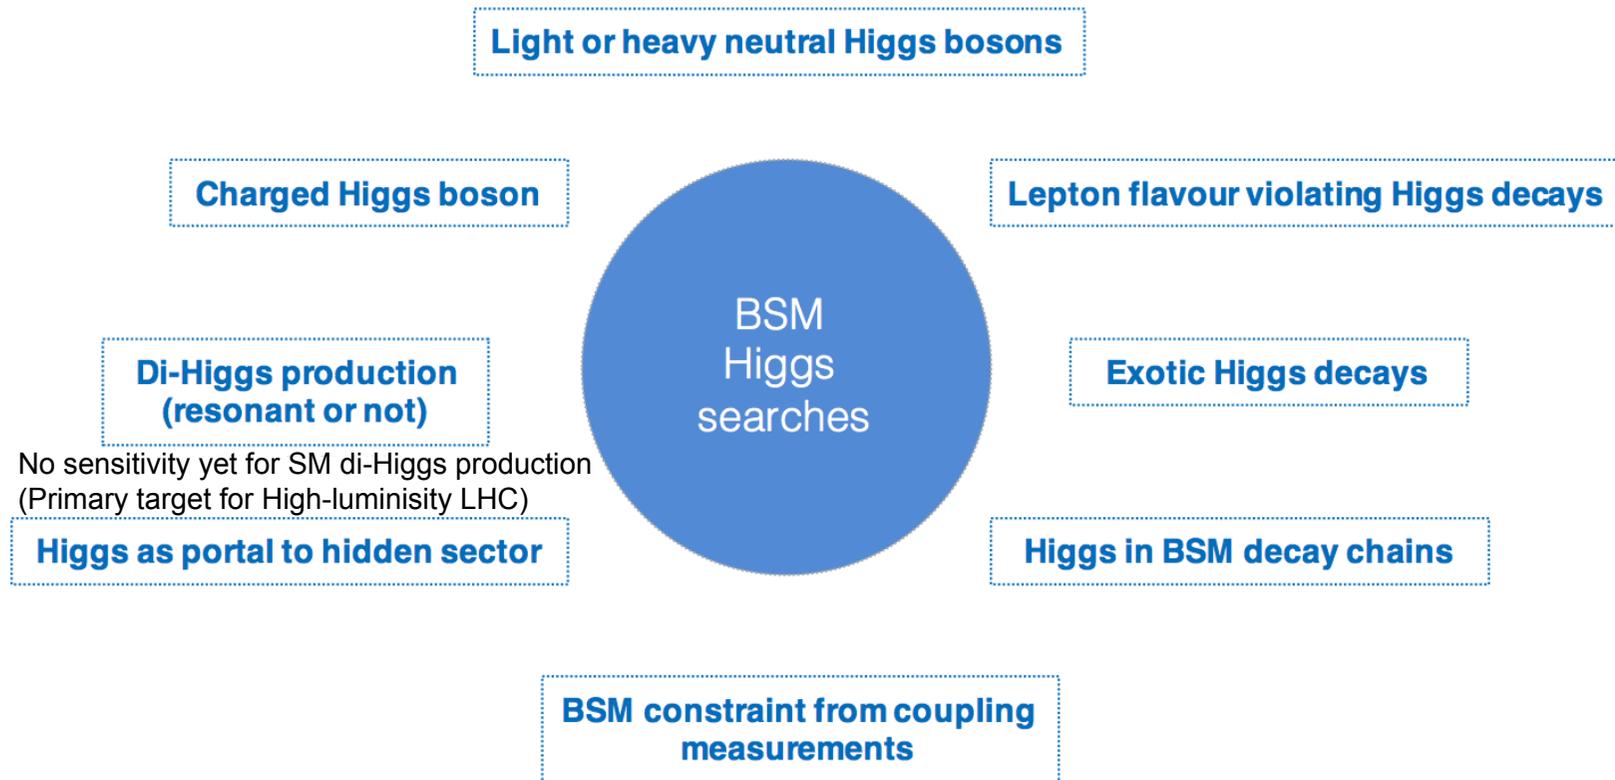

- Beyond SM reach at present, but could have New Physics contributions?
 - Strongly resolution dependent, improve sensitivity by categorising events (low/high p , central/forward, VBF)
 - Obs limit: 4.4 times SM. Needs $\sim 300 \text{ fb}^{-1}$ data to reach SM (Run3)

- Can already exclude universal Higgs coupling to fermions
 - Would have observed $H \rightarrow \mu\mu$, if same BR as $H \rightarrow \tau\tau$

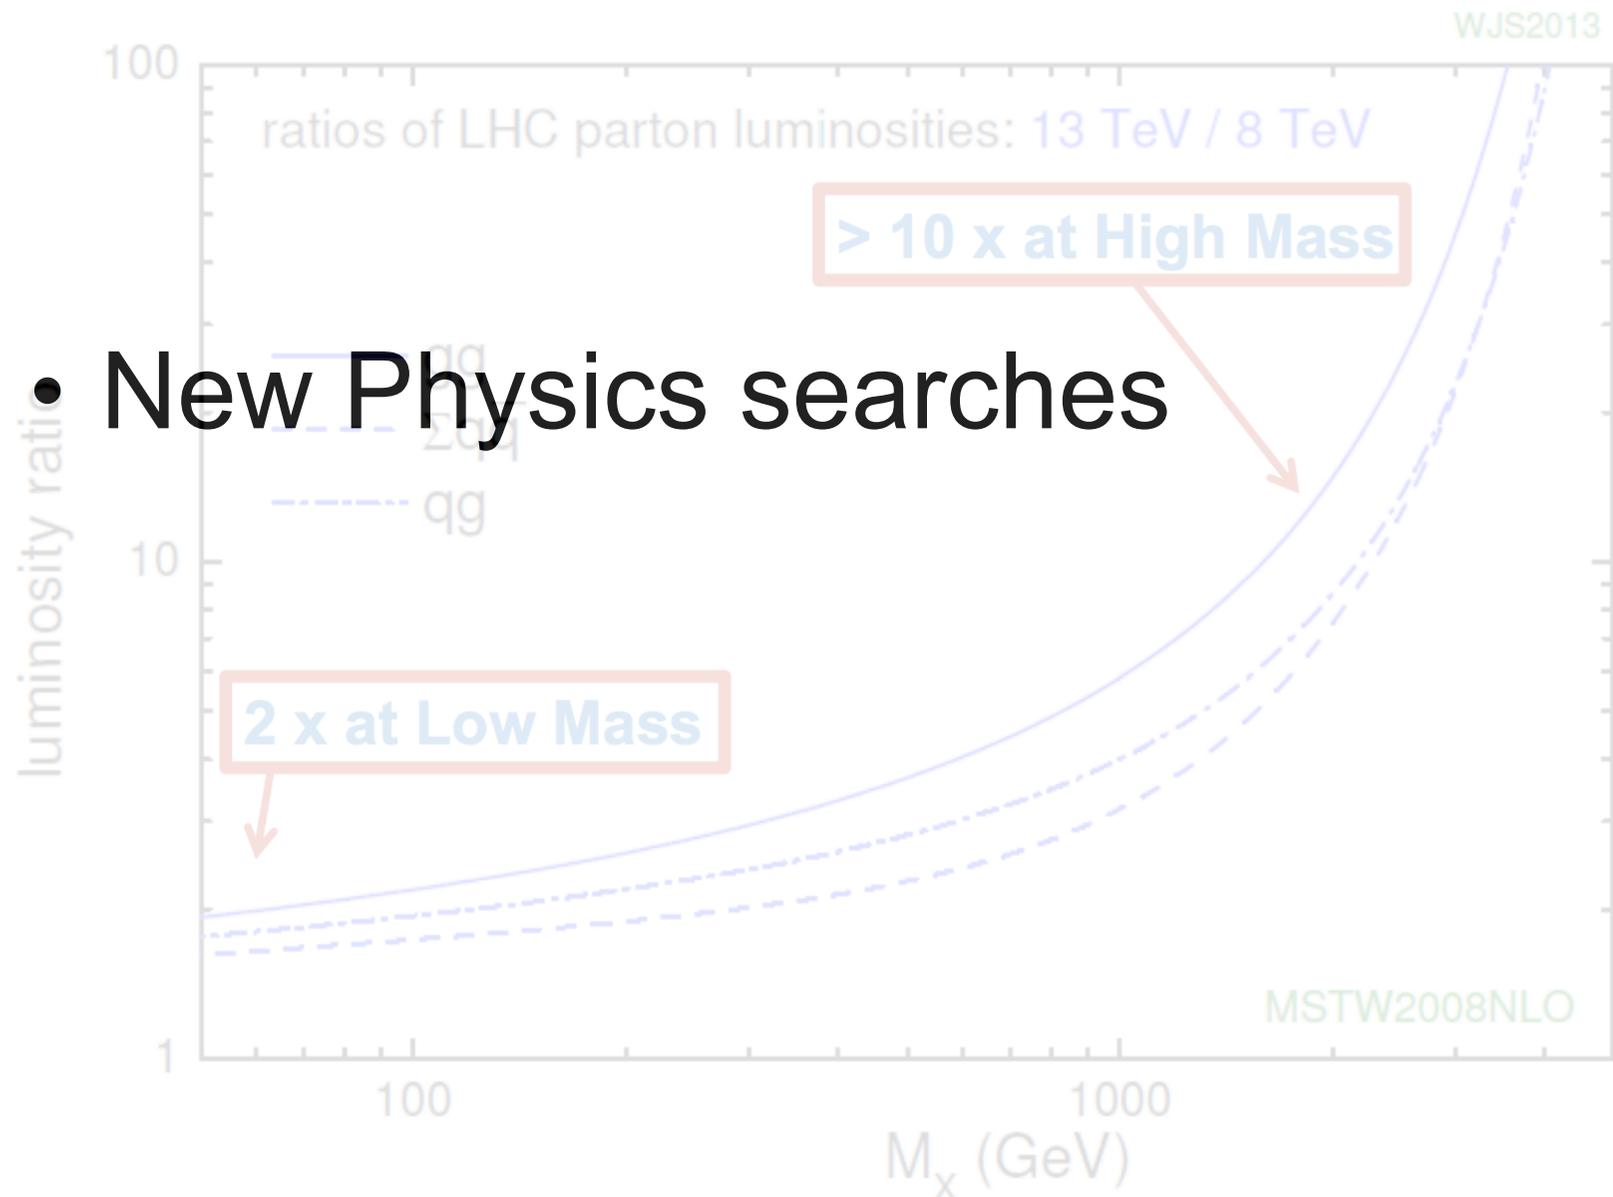

Beyond the Standard Model Higgs physics

- Higgs sector may be non-minimal and/or Higgs boson may couple to New Physics
- Diverse search program is in place;

No deviations from SM found in any of these searches

Taken from: Thibault Guillemin @SEARCH 2016

- New Physics searches

New Physics searches in Run2

- Broad search program
 - from inclusive surveys of basic event topologies
 - to dedicated searches ruling out corners of phase space
- Major extension of reach compared to Run1
- All results shown here include 2016 data
- They probe well into the TeV, even multi-TeV, mass scale range

Exploring Exotics

- **Guiding physics models**

- Technicolor
- Warped Extra Dimensions
- Grand Unified Theories
- Heavy Vector Triplet
- Quantum Black Holes
- Hidden valley
- Contact Interactions
- Compositeness
- Exotic Fermions
- Leptoquarks
- ...

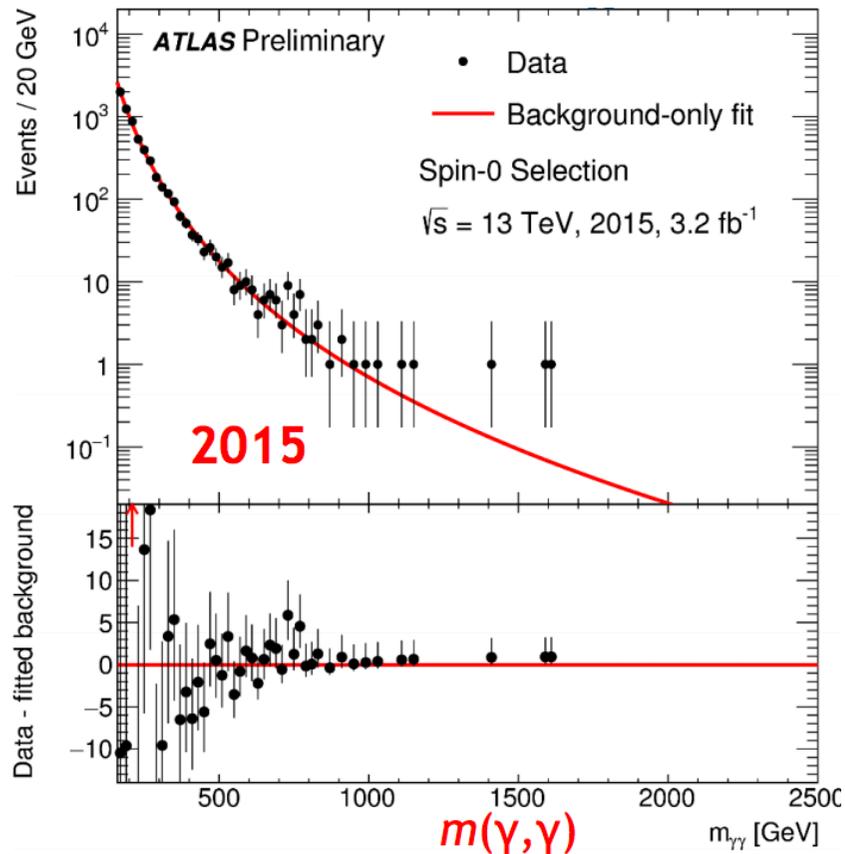

- **Signatures**

- Di-lepton / di-jet / di-b-jet resonances (Z' , W' , ...)
- Di-boson resonances
 - $WZ, ZZ, W\gamma, Z\gamma$
- Multi-jet resonances
- tb, Ht, Zt, Zb (Z', W', T, B, \dots)
- Processes in high tails (non-resonances)
- Long lived particles
- Large missing energy
- ...

- One model with different signatures
- One signature probing various models

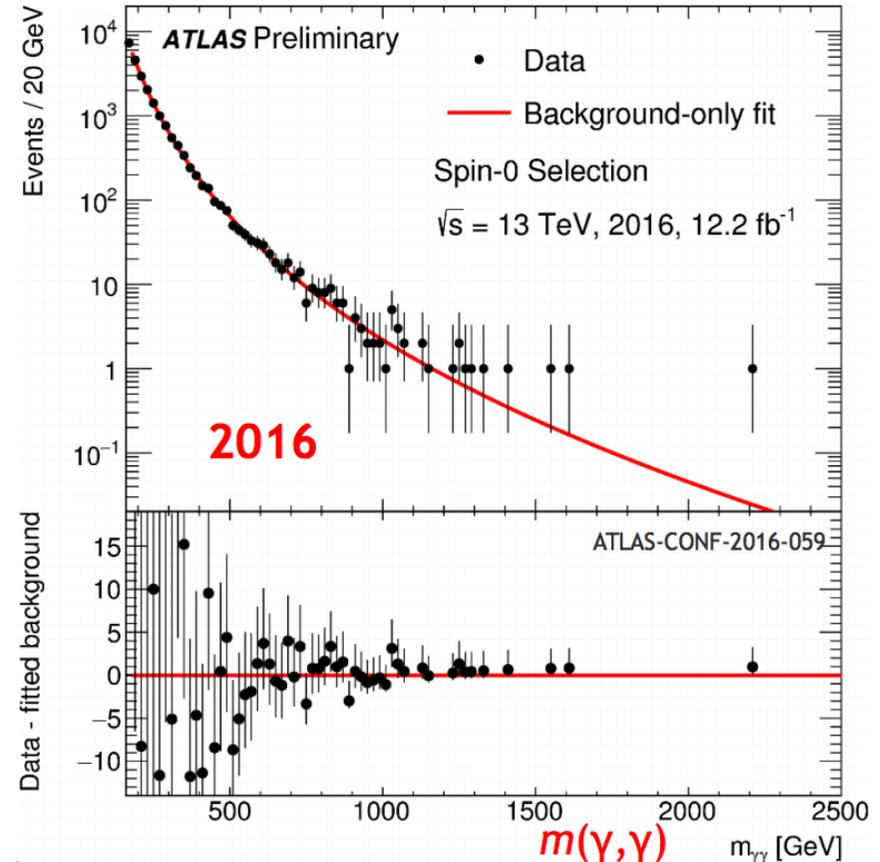

→ Search as broad and general as possible (signatures, masses, rates) covering physics without guiding models

Di-photon searches

2015 ATLAS data: localised excess seen

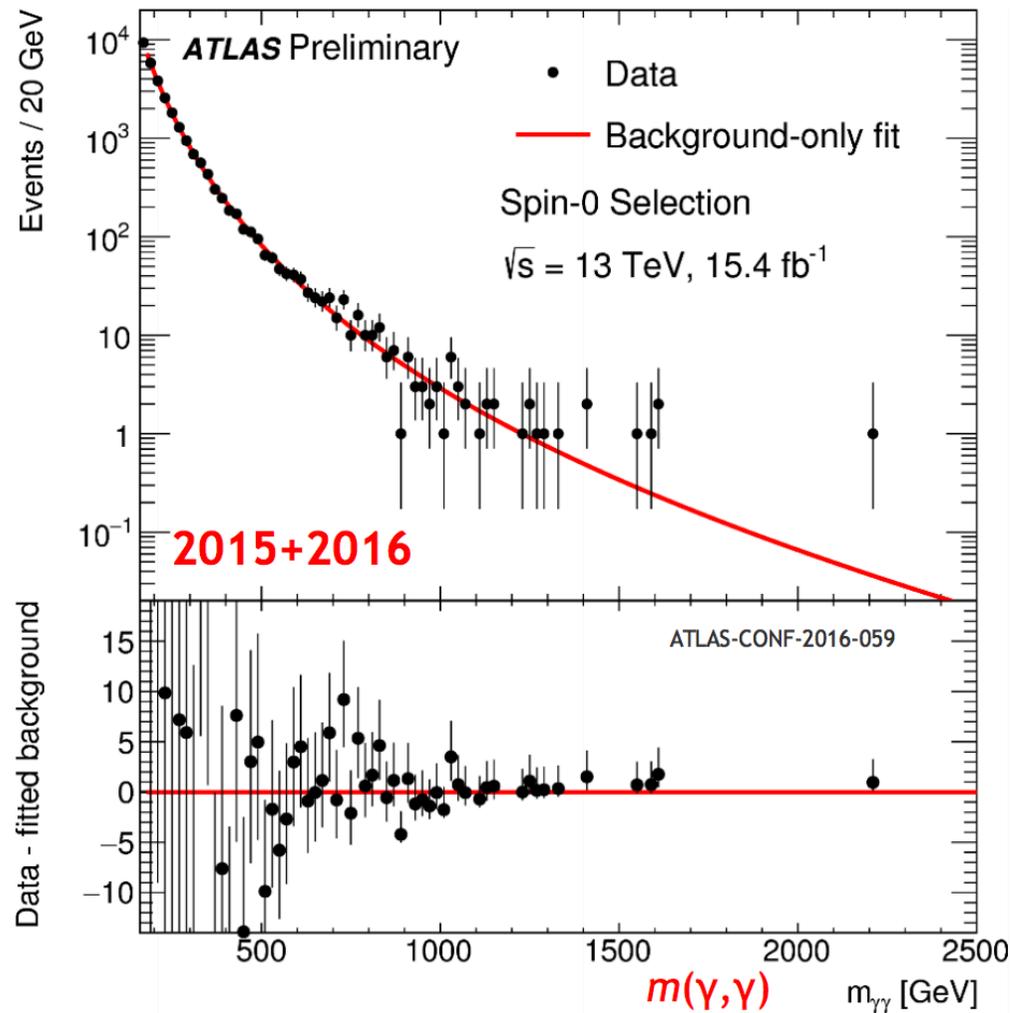

- 2.1σ global (3.9σ local) significance at 750 GeV (spin-0 search), width ~ 50 GeV

2016 data: no clustering around 730-750 GeV, and 3.8x more data

- 2016 data consistent with 2015 at 2.7σ
- Appears that the 2015 excess was a statistical fluctuation

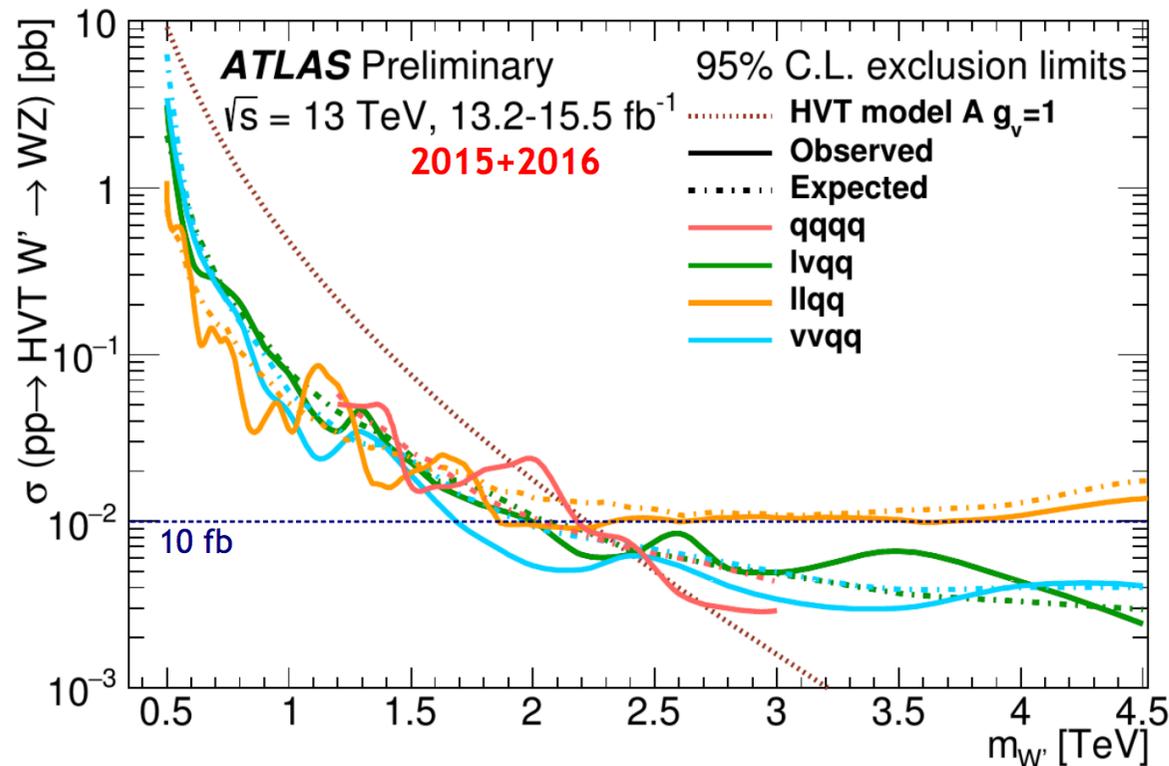

Finally with 2015+2016 data

- Small excess at 710 GeV ($\Gamma/m \sim 10\%$)
- Local significance 1.4σ , global $< 1\sigma$

Massive di-boson searches

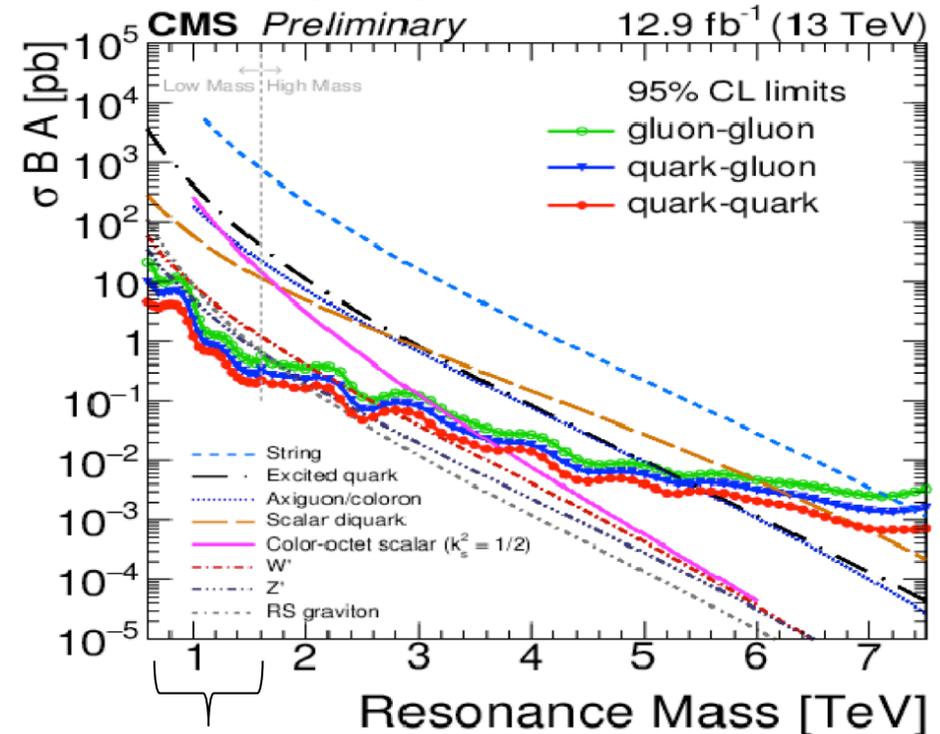

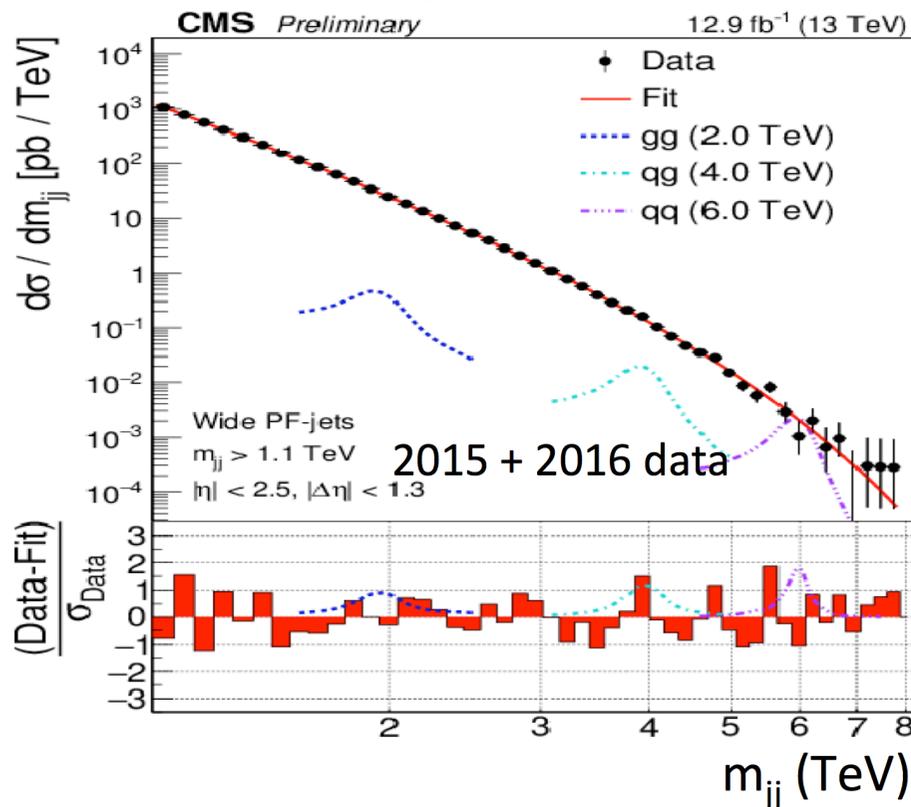

- Search for resonant di-boson production
 - Boosted (“fat jet”) selections vital at high- p_T
 - Explored many channels with 2016 data

- Overlaying limits from all WZ searches – no persistent excesses, in contrary to the Run1 excesses

Di-jet searches

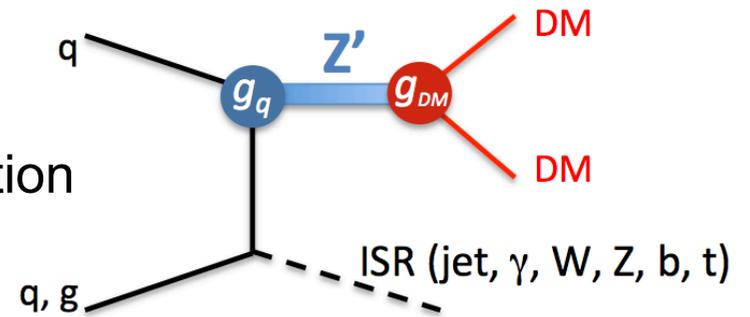

- Search for New Physics in di-jet mass spectrum; bump hunter
 - Di-jet: qq, qg, gg (high mass > ~1 TeV). High priority in early Run2
 - Sensitivity based on signal shapes including large low mass tails

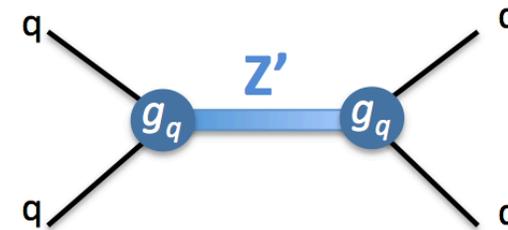

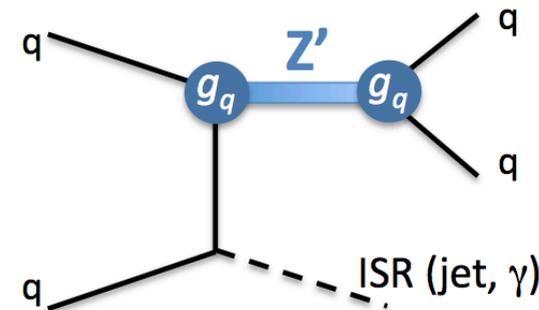

For low-mass search, a dedicated trigger technique “data scouting at trigger level” allowed lower threshold by keeping partial info. and online calibration

Di-jet searches: Dark Matter Interpretation

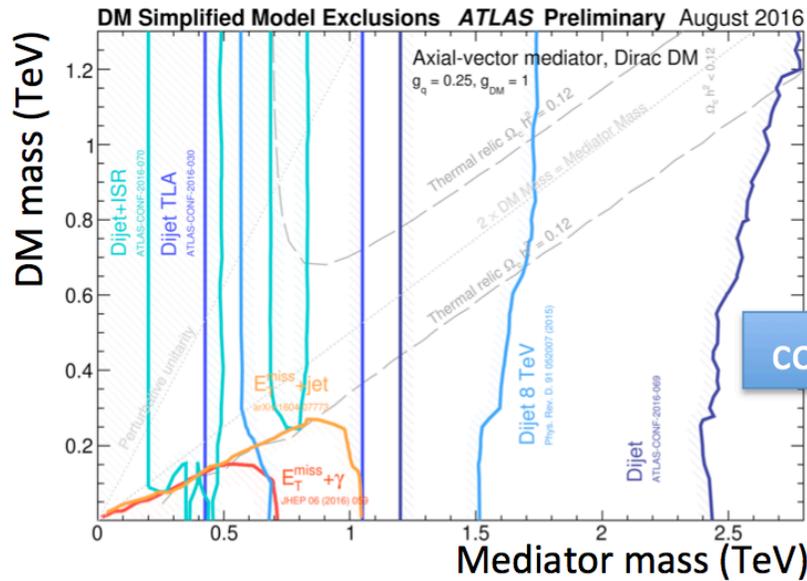

- Complementary to mono-(jet, γ , W , Z , b , t , H , ...) searches
 - Tag DM pair (E_T^{miss}) via Initial state radiation
 - Mediator (Z') mixing with Z , H

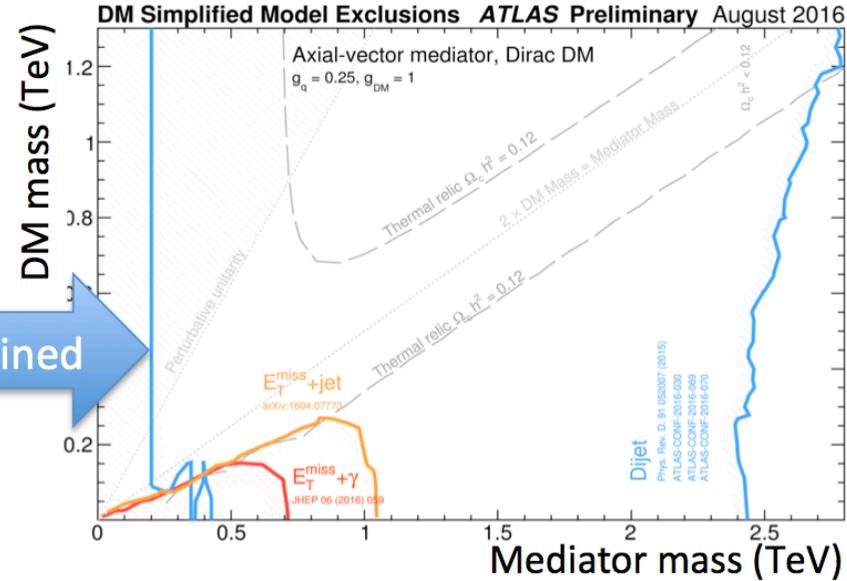

- Mediator (Z')
 - Couples to quarks (g_q) and DM (g_{DM})
 - Dijet searches cover a broad mediator mass range
 - DM interpretation of Z' searches

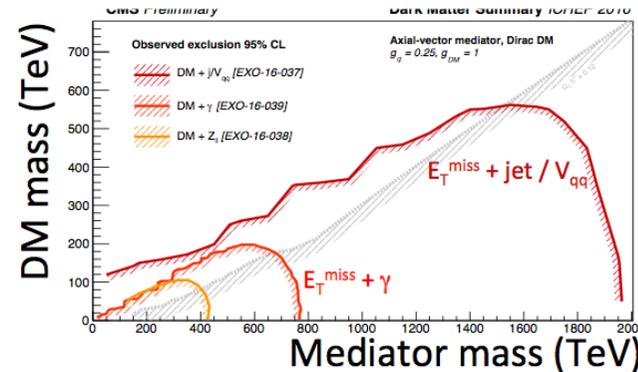

Di-jet searches: Dark Matter Interpretation

combined

$$g_q = 0.25, g_{DM} = 1$$

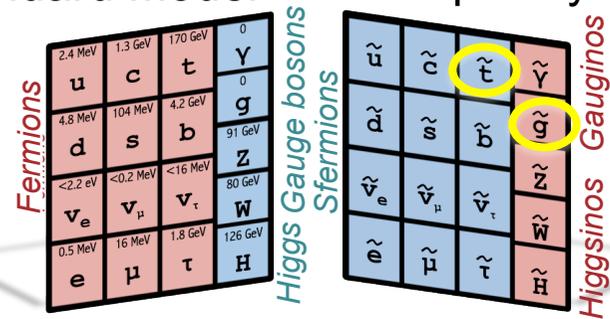

- Complementary to mono-X searches; cover a broad mediator mass range – Results highly depend on choice of coupling parameters ($L = g_q \gamma^\mu q Z'_\mu$)

SUSY searches

- The case for SUSY is well known
 - Natural Dark Matter candidate in *neutralino1*
 - Can solve the fine-tuning problem – if $t\tilde{}$ and $g\tilde{}$ are light

the Standard Model the Super Symmetry

- In Run1 we identified:
 - $m(g\tilde{}) > 1.4\text{TeV}$ for low-mass *neutralino1*
 - $m(t\tilde{}) > 700\text{GeV}$ if $m(\text{neutralino1}) < 100\text{GeV}$
- Run2 priorities:
 - Extend mass reach according to \sqrt{s} increase
 - Fill “kinematic holes” where particles are soft
 - “Leave no stone unturned” e.g. displaced decays from long-lived particles

SUSY search results

ATLAS SUSY Searches* - 95% CL Lower Limits

Status: August 2016

Run1 data Run2 data

*Only a selection of the available mass limits on new states or phenomena is shown.

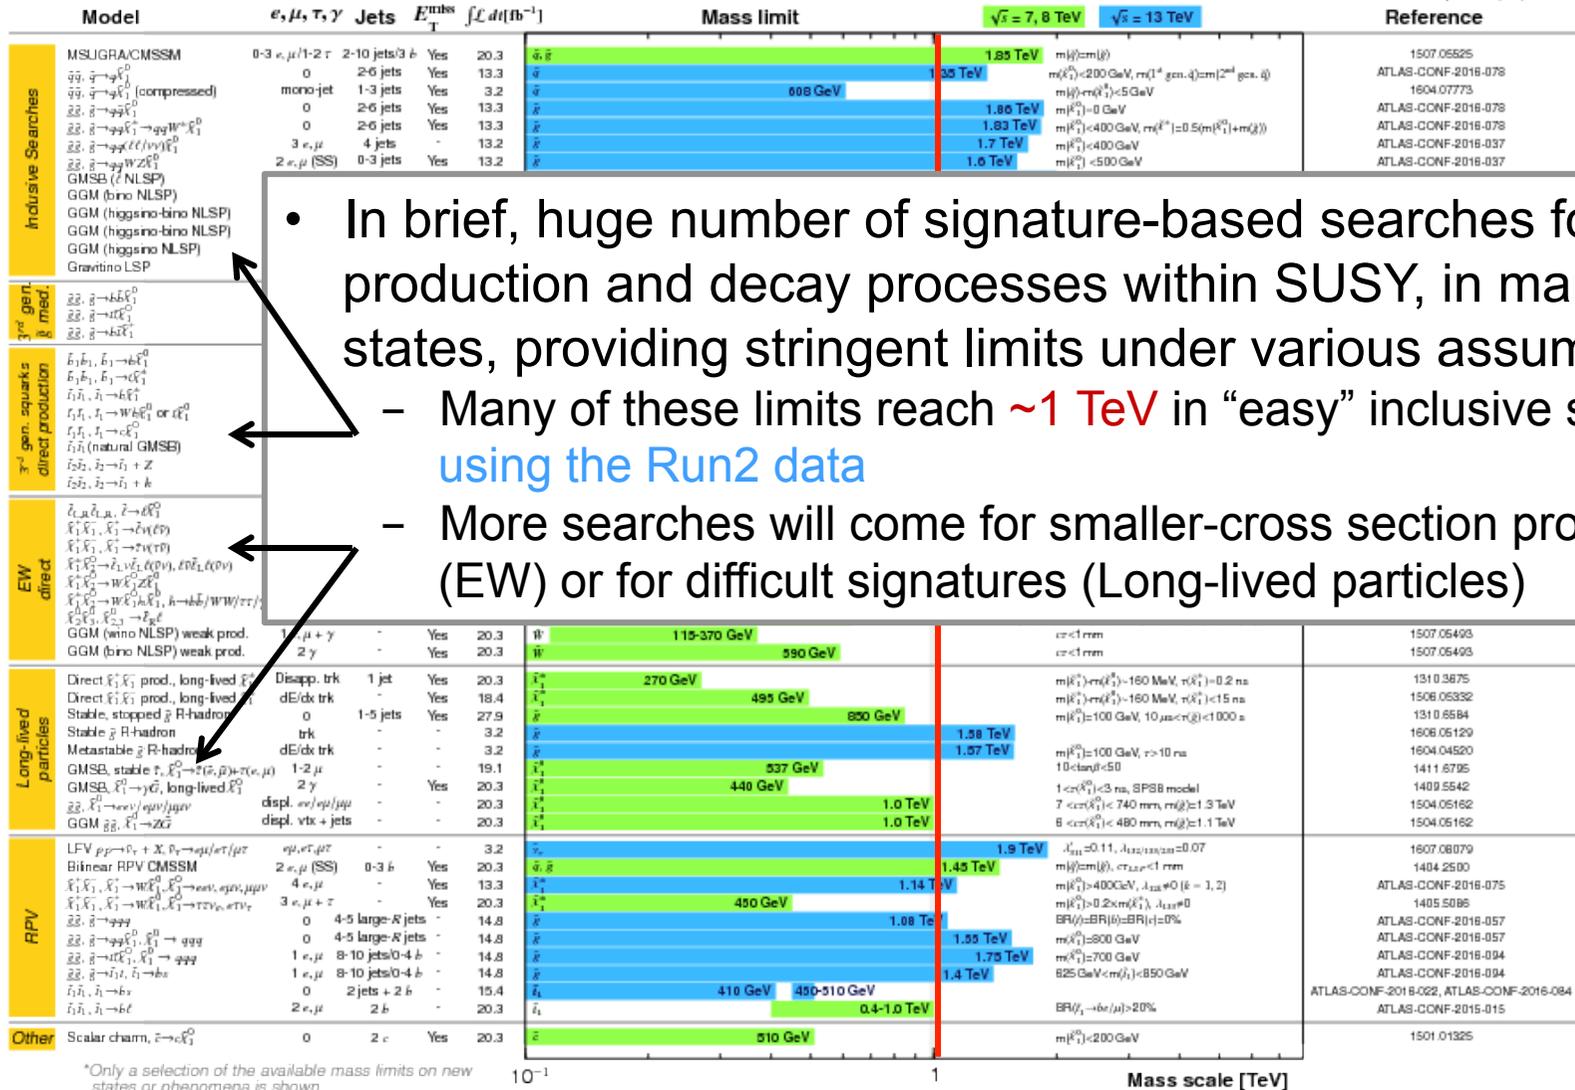

10⁻¹ 1 Mass scale [TeV]

SUSY search results

ATLAS SUSY Searches* - 95% CL Lower Limits
Status: August 2016

Run1 data Run2 data

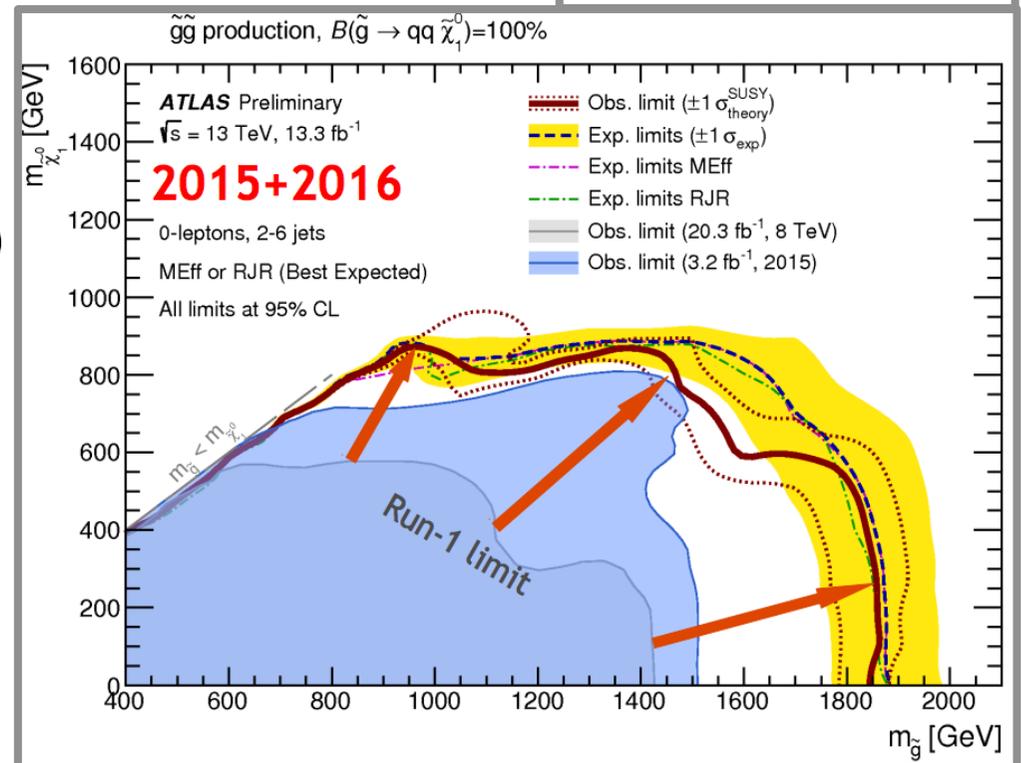

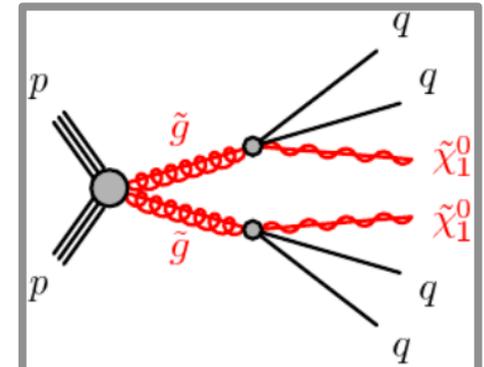

ATLAS Preliminary
 $\sqrt{s} = 7, 8, 13$ TeV

*Only a selection of the available mass limits on new states or phenomena is shown.

Example: $g\tilde{}/q\tilde{}$ search with jets+ E_T^{miss}

- Event selection: require 2-6 jets and veto isolated leptons
 - Sensitive to $g\tilde{}$ and $q\tilde{}$ production
 - High priority in early Run2
- Total of 30 signal regions to cover various mass spectra
 - No significant excesses in any signal region overall
 - For small $m(\text{neutralino1})$ exclusion reach extended $m(g\tilde{}) < 1.4 \text{ TeV}$ (Run1) $\rightarrow < 1.86 \text{ TeV}$ (2015+16)
 - Check details in poster by Y. Sano (a Nagoya PhD student)

Conclusion

- The LHC is performing extremely well
- A broad range of LHC Run2 results using early 2016 dataset
 - Starting precise measurements of H(125) at 13 TeV
 - Concluding on the Standard Model ttH sensitivity
 - 13 TeV in Run2 brings significant increase in sensitivity, shaping the search program in 2015 and early 2016
 - The limits set significantly extend the Run1 results, thus further constraining various models. No significant excesses, though some $\sim 3\sigma$ effects as expected. More data will tell which, if any, will remain
 - The search program is moving toward more challenging signatures and scenarios
- Expecting exciting future
 - New results with $\sim 40 \text{ fb}^{-1}$ in early spring of 2017
 - Data analysed so far: a small fraction of total Run2 (100 fb^{-1})

- Backup slides

pMSSM scans

- LHC: simplified model \rightarrow BR=1 (even for cascade decays)
- setting limits on various pMSSM using all ATLAS search

results in Run1

- Good coverage of pMSSM, dependence on LSP nature (via signatures)

- Similar scan will be repeated with results using the Run2 full dataset
